

• Clustering in DBMS

- Here S1, S2 & S3 are ^{database which store} replicas ~~data~~ of data sets.
- Here redundancy is useful to overcome the problem of overload of server and ^{there} ~~prevent~~ website down.
- Database clustering is the process of combining more than one server ~~for~~ connecting a single database.
- Some advantages are given below:-
 - ① load balancing, distribution of requests across multiple servers, which prevents any single server from being overwhelmed.
 - ② High availability, clustering ensures that the system remains operational even if one or more server fails.

Partitioning & Sharding in DBMS DB optimisation

- A big problem can be solved when it is broken down into smaller parts. This technique is known as partitioning technique.

Partitioning

- A technique to divide the stored database objects into separate servers. Due to this, there is an increase in performance.

- Two types of partitioning:-
 (i) Horizontally

					Server 1
	id	Name	address	Phone	
	1	-	-	-	✓
	2	-	-	-	
	3	-	-	-	
	4	-	-	-	

↑
Server 2

- Slicing relation horizontally / row-wise
- Independent chunks of data tuple are stored in different servers.

② Vertically

id	Name	address	Phone
1			
2			
3			
4			
Server 1		Server 2	

- Slicing relation vertically / column-wise.
- Need to access different servers to get complete tuples.

③ Why partitioning?

Ans. Dataset become much huge that managing and dealing with it become a tedious task.

- The number of requests are enough larger than the single DB server access is taking huge time.
- Advantages:- Parallelism, availability, Performance, Reduce cost.
- Distributed database:- A single database is spread across multiple locations.
Eg. → clustering, Partitioning and Sharding.
- Sharding:- Technique to implement horizontal partitioning.
- Instead of keeping DB on one instance, split it and use a Routing layer to forward the request to the right instance.
