Note:- If a write request goes to slave database then it either decline that or forward it to the master database. If it forward this then it is a Master-Master Database System.

The Master - Slave Database Concept

- Here in database architecture, master database will perform the "write" operations and the other two databases (slaves) will replicate it. The "read" perform by the slave database.

- This will increase the efficiency of the databas.

- In, case of Banking System on this model, the master database will show success of transactions only after it replicate to slave database.

- In case of Facebook, it will show delay update.
